Graph Neural Network (GNN)

A graph $G = (V, E, \omega)$ is a set of triplets with vertices $V = \{v_i\}_{i=1}^{S_0}$, edges $E \subseteq V \times V$, and edge weight function $\omega : E \to \mathbb{R}$. The graph has an adjacency matrix A with the (i, j) th entry $a_{ij} = \omega (v_i, v_j)$. Each node has a d-dimensional feature, and we collect the feature vectors into a matrix $H^{\text{in}} \in \mathbb{R}^{S_0 \times d}$. A common GNN convolutional layer has the form

$$H^{\mathsf{out}} = \psi \left(\mathcal{H} \left(A, H^{\mathsf{in}} \right) W_{\mathsf{0}}
ight),$$

where ψ is the activation function, $\mathcal{H}(A, H)$ is an aggregation mapping, and $W_0 \in \mathbb{R}^{d \times m}$ are the trainable weights.

Graph Neural Networks (GNNs)

Expressive Power of GNN

Graph Isomorphism Test:

- Two graphs are considered isomorphic if there is a mapping between the nodes of the graphs that preserves node adjacencies.
- Expressive power is whether can detect isomorphic graphs.

Expressive Power by Linear Regions

Experiments

Precisely how hard the graph isomorphism problem is remains an open question in computer science.

The 1-WL Algorithm:

- For iteration *i*, we assign to each node a tuple *L*_{*i*,*n*} containing the nodes old compressed label *C*_{*i*-1,*n*} and a multiset of the nodes neighbors' previous labels.
- Hash $L_{i,n}$ to a new label $C_{i,n}$. Any two nodes with the same $L_{i,n}$ will get the same compressed label.
- Partition the nodes in the graph assigned label and repeat above for *N* (the number of nodes) iterations, or until there is no change in the partition of nodes.

It produces each graph a canonical form. If the canonical forms of two graphs are not equivalent, then the graphs are definitively not isomorphic. However, it is possible for two non-isomorphic graphs to share a canonical form.

WL Test and GNN

GNN with injective aggregating function is equivalent in its expressive power to the WL test (Xue et al., 2019).

However, limited in their capability of detecting graph structures such as triangles or cliques (Chen et al., 2020).

Figure: Two graphs that cannot be distinguished by 1-WL, but have distinct clique complexes (the second contains triangles).

Introduce simplicial complex for better expressive power.

Background on Simplicial Complexes

Definition (simplicial complex)

Let V be a non-empty vertex set. A **simplicial complex** \mathcal{K} is a collection of nonempty subsets of V that contains all the singleton subsets of V and is closed under the operation of taking subsets.

A member $\sigma = \{v_0, \dots, v_k\} \in \mathcal{K}$ with cardinality k + 1 is called a k-dimensional simplex or simply a k-simplex.

E.g. 0-simplices as vertices, 1-simplices as edges, 2-simplices as triangles, and so on.

Definition (Boundary incidence relation)

We say $\sigma \prec \tau$ iff $\sigma \subset \tau$ and there is no δ such that $\sigma \subset \delta \subset \tau$.

Definition (Orientation)

An oriented k-simplex is a k-simplex with a chosen order for its vertices. An oriented k-simplex is positively oriented if its vertices form an even permutation and negatively oriented otherwise.

ヘロマ スぽく メヨマ メヨマ

Hodge Laplacian

The oriented boundary relations \prec_+, \prec can be encoded by the signed boundary matrices (or incidence matrix) $B_k \in \mathbb{R}^{S_{k-1} \times S_k}$ has entries

$$B_k(i,j) = \begin{cases} 1, \text{ if } \tau_i \prec_+ \sigma_j \\ -1, \text{ if } \tau_i \prec -\sigma_j \\ 0, \text{ otherwise} \end{cases}$$

where dim $(\sigma_j) = k$, dim $(\tau_i) = k - 1$, and S_k denotes the number of simplices of dimension k.

Definition (Hodge Laplacian)

The k-th Hodge Laplacian of the simplicial complex, a diffusion operator for signals over the oriented k-simplices, is defined as

$$L_k = B_k^\top B_k + B_{k+1} B_{k+1}^\top$$

Note that L_0 gives the well-known graph Laplacian.

Expressive Power by Linear Regions

Experiments

Simplicial WL (SWL) Test

Steps of SWL in the most general sense:

- Given a complex \mathcal{K} , all the simplices $\sigma \in \mathcal{K}$ are initialized with the same colour.
- Q Given the color c^t_σ of simplex σ at iteration t, we compute the color of simplex σ at the next iteration c^{t+1}_σ, by perfectly hashing the multi-sets of colors belonging to the adjacent simplices of σ.
- The algorithm stops once a stable coloring is reached. Two simplicial complexes are considered nonisomorphic if the color histograms at any level of the complex are different.

Key: what simplices are considered to be adjacent

Types of Adjacencies

Definition (Adjacent Simplices)

Consider a simplex $\sigma \in \mathcal{K}$. Four types of adjacent simplices can be defined:

- Boundary adjacencies: $\mathcal{B}(\sigma) = \{\tau \mid \tau \prec \sigma\}.$
- **2** Co-boundary adjacencies: $C(\sigma) = \{\tau \mid \sigma \prec \tau\}.$
- Solution Lower-adjacencies: $\mathcal{N}_{\downarrow}(\sigma) = \{\tau \mid \exists \delta, \delta \prec \tau \land \delta \prec \sigma\}$
- Upper-adjacencies: $\mathcal{N}_{\uparrow}(\sigma) = \{\tau \mid \exists \delta, \tau \prec \delta \land \sigma \prec \delta\}$

The boundary simplices of an edge: its vertices The co-boundary simplices of a vertex: the edges connected with The lower-adjacent edges: share a vertex The upper adjacencies between vertices: part of the same line

イロト 不得 トイヨト イヨト 二日

The Multisets in SWL

Definition

Let c^t be the coloring of SWL for the simplices in \mathcal{K} at iteration t. We define the following multi-sets of colors, corresponding to each type of adjacency:

$$c_{\mathcal{B}}^{t}(\sigma) = \{ \{ c_{\tau}^{t} \mid \tau \in \mathcal{B}(\sigma) \} \}$$

$$c_{\mathcal{C}}^{t}(\sigma) = \{ \{ c_{\tau}^{t} \mid \tau \in \mathcal{C}(\sigma) \} \}.$$

イロン イヨン イヨン イヨン

SWL Update Rule

The SWL update rule with the complete set of adjacencies:

$$c_{\sigma}^{t+1} = \mathsf{HASH}\left\{c_{\sigma}^{t}, c_{\mathcal{B}}^{t}(\sigma), c_{\mathcal{C}}^{t}(\sigma), c_{\downarrow}^{t}(\sigma), c_{\uparrow}^{t}(\sigma)\right\}$$

Theorem

SWL with HASH $(c^t_{\sigma}, c^t_{\mathcal{B}}(\sigma), c^t_{\uparrow}(\sigma))$ is as powerful as SWL with the generalized update rule HASH $(c^t_{\sigma}, c^t_{\mathcal{B}}(\sigma), c^t_{\uparrow}(\sigma), c^t_{\uparrow}(\sigma))$.

Reduces to WL when applied to graphs and only considers vertex coloring. "this result comes from a (theoretical) color-refinement perspective and it does not imply that the pruned adjacencies cannot be useful in practice."

Link the Expressive Power of WL and SWL

Definition

The **clique complex** of a graph *G* is the simplicial complex \mathcal{K} with the property that if nodes $\{v_0, \ldots, v_k\}$ form a clique in *G*, then simplex $\{v_0, \ldots, v_k\} \in \mathcal{K}$. In other words, every (k + 1)-clique in *G* becomes a *k*-simplex in \mathcal{K} . This is called a **lifting transformation**.

Theorem

SWL with a clique complex lifting is strictly more powerful than WL.

As illustrated by the previous example:

Link the Expressive Power of WL and SWL

Theorem

SWL is not less powerful than 3-WL.

Figure: Rook's 4x4 graph and the Shrikhande graph: Strongly Regular non-isomorphic graphs with parameters SR(16, 6, 2, 2). SWL can distinguish them: only Rook's graph (left) possesses 4 -cliques (orange) and thus the two graphs are associated with distinct clique complexes. The 3-WL test fails to distinguish them.

Experiments

Message Passing Simplicial Networks (MPSN)

Message passing model using the following message passing operations based on the four types of multisets. For a simplex σ in a complex K we have:

$$\begin{split} m_{\mathcal{B}}^{t+1}(\sigma) &= \operatorname{AGG}_{\tau \in \mathcal{B}(\sigma)} \left(M_{\mathcal{B}} \left(h_{\sigma}^{t}, h_{\tau}^{t} \right) \right) \\ m_{\mathcal{C}}^{t+1}(\sigma) &= \operatorname{AGG}_{\tau \in \mathcal{C}(\sigma)} \left(M_{\mathcal{C}} \left(h_{\sigma}^{t}, h_{\tau}^{t} \right) \right) \\ m_{\downarrow}^{t+1}(\sigma) &= \operatorname{AGG}_{\tau \in \mathcal{N}_{\downarrow}(\sigma)} \left(M_{\downarrow} \left(h_{\sigma}^{t}, h_{\tau}^{t}, h_{\sigma \cap \tau}^{t} \right) \right) \\ m_{\uparrow}^{t+1}(\sigma) &= \operatorname{AGG}_{\tau \in \mathcal{N}_{\uparrow}(\sigma)} \left(M_{\uparrow} \left(h_{\sigma}^{t}, h_{\tau}^{t}, h_{\sigma \cup \tau}^{t} \right) \right) . \end{split}$$

and the update operation takes into account these four types of incoming messages and the previous color of the simplex:

$$h_{\sigma}^{t+1} = U\left(h_{\sigma}^{t}, m_{\mathcal{B}}^{t}(\sigma), m_{\mathcal{C}}^{t}(\sigma), m_{\downarrow}^{t+1}(\sigma), m_{\uparrow}^{t+1}(\sigma)\right).$$

イロト 不得 トイヨト イヨト

Expressive Power of MPSN

Theorem

MPSNs with sufficient layers and injective neighborhood aggregators are as powerful as SWL.

Corollary

There exists an MPSN that is more powerful than WL at distinguishing non-isomorphic graphs when using a clique-complex lifting.

In particular, based on previous Theorem, it is sufficient for such an MPSN to use boundary and upper adjacencies.

イロン イ団 とく ヨン イヨン

Relation to Spectral Convolutions

GNNs are known for their relationship with spectral convolution operators on graphs obtained via graph Laplacian (Hammond et al., 2011). Analogously to this, MPSNs generalize certain spectral convolutions on graphs derived from the higher-order simplicial Hodge Laplacian

Theorem

Theorem 12. MPSNs generalize certain spectral convolution operators (Ebli et al., 2020; Bunch et al., 2020) defined over simplicial complexes.

4 Expressive Power by Linear Regions

Experiments

Expressive Power by Linear Regions

The number of linear regions using piece-wise linear activations has been used to study conventional neural networks.

Figure: A 2D slice of the input feature spaces of GNN, SCNN, MPSN layers with $S_0 = S_1 = 3, S_2 = 1$ (the complex is a triangle), $d_0 = d_1 = d_2 = 1, m = 3$, colored by linear regions of the represented functions, for a random choice of the weights.

(日)

Graph Neural Network (GNN)

The graph has an adjacency matrix A. Each node has a d-dimensional feature, and we collect the feature vectors into a matrix $H^{in} \in \mathbb{R}^{S_0 \times d}$. We consider a GNN convolutional layer of the form

$$H^{\mathsf{out}} = \psi \left(\mathcal{H} \left(A, H^{\mathsf{in}} \right) W_0 \right),$$

where ψ is the entry-wise ReLU, $\mathcal{H}(A, H)$ is an aggregation mapping, and $W_0 \in \mathbb{R}^{d \times m}$ are the trainable weights.

イロト 不得 トイヨト イヨト

GNN Linear Regions

Theorem (Number of linear regions of a GNN layer)

Consider a graph G with S_0 nodes, node input features of dimension $d \ge 1$, and node output features of dimension m. Suppose the aggregation function \mathcal{H} as function of H is linear and invertible. Then, the number of linear regions of the functions represented by a ReLU GNN layer has the optimal upper bound

$$R_{\mathrm{GNN}} = \left(2\sum_{i=0}^{d-1} \left(egin{array}{c} m-1 \ i \end{array}
ight)
ight)^{S_0}$$

To compare: the optimal upper bound for a standard dense ReLU layer without biases with *d* inputs and *m* outputs is $2\sum_{i=0}^{d-1} \binom{m-1}{i}$

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

Simplicial Complex Neural Networks (SCNNs)

Consider a version of the model in Ebli et al. (2020) using only the first power of a Laplacian matrix, generically denoted here by M_n :

$$H_n^{\text{out}} = \psi \left(M_n H_n^{\text{in}} W_n \right), \quad n = 0, \dots, p$$

where the features on simplices of different dimensions n = 0, 1..., p are computed in parallel.

Definition (Number of linear regions for an SCNN layer)

Consider a *p*-dimensional simplicial complex with $S_n n$ simplicies for n = 0, 1, ..., p. Suppose that each M_n is invertible. Then the number of linear regions of the functions represented by a ReLU SCNN layer has the optimal upper bound

$$R_{\rm SCNN} = \prod_{n=0}^{p} \left(2 \sum_{i=0}^{d_n-1} \begin{pmatrix} m_n-1 \\ i \end{pmatrix} \right)^{S_n}$$

where, for each of the n-simplices, d_n is the input feature dimension and m_n is the number of output features.

・ロト ・回ト ・ヨト ・ヨト

MPSN Formulation

For a *p*-dimensional complex, denote the set of *n*-simplices by S_n with $S_n = |S_n|$. Denote the *n*-simplex input feature dimension by d_n , and the output feature dimension by $m_n = m, n = 0, ..., p$. We consider an MPSN layer with

- linear message functions
- sum aggregation for all messages
- an update function taking the sum of the messages followed by a ReLU activation

For each dimension *n*, the output feature matrix H_n^{out} equals:

$$\psi\left(M_nH_n^{\mathrm{in}}W_n+U_nH_{n-1}^{\mathrm{in}}W_{n-1}+O_nH_{n+1}^{\mathrm{in}}W_{n+1}\right),$$

where ψ is an entry-wise activation, $W_n \in \mathbb{R}^{d_n \times m_n}$ are trainable weight matrices and $M_n \in \mathbb{R}^{S_n \times S_n}$, $U_n \in \mathbb{R}^{S_n \times S_{n-1}}$, and $O_n \in \mathbb{R}^{S_n \times S_{n+1}}$ are some choice of adjacency matrices for the simplicial complex.

イロト イロト イヨト イヨト 二日 二

MPSN in Standard Form

Roth's lemma (Roth, 1934) states

$$\operatorname{vec}\left(M_{n}H_{n}^{\operatorname{in}} W_{n}
ight)=\left(W_{n}^{ op}\otimes M_{n}
ight)\cdot\operatorname{vec}\left(H_{n}^{\operatorname{in}}
ight)$$

where vec denotes column-by-column vectorization and \otimes the Kronecker product. Using Roth's lemma and concatenating over *n* we can write as

$$H^{\text{out}} = \psi \left(WH^{\text{in}} \right),$$

$$H^{\text{in}} = \text{vec} \left(\begin{bmatrix} H_0^{\text{in}} | H_1^{\text{in}} | \cdots | H_p^{\text{in}} \end{bmatrix} \right) \in \mathbb{R}^N, N = \sum_{n=0}^p S_n d_n,$$

$$H^{\text{out}} = \text{vec} \left(\begin{bmatrix} H_0^{\text{out}} | H_1^{\text{out}} | \cdots | H_p^{\text{out}} \end{bmatrix} \right) \in \mathbb{R}^M, M = \sum_{n=0}^p S_n m, \text{ and}$$

$$W = \begin{bmatrix} W_0^\top \otimes M_0 & W_1^\top \otimes O_0 \\ W_0^\top \otimes U_1 & W_1^\top \otimes M_1 & W_2^\top \otimes O_1 \\ & & W_1^\top \otimes U_2 & W_2^\top \otimes M_2 & W_3^\top \otimes O_2 \\ & & & \ddots \end{bmatrix} \in \mathbb{R}^{M \times N}$$

3

MPSN Linear Regions

Theorem (Number of linear regions of an MPSN layer)

With the above settings, the maximum number of linear regions of the functions represented by a ReLU MPSN layer is upper bounded by

$$R_{ ext{MPSN}} \leq \prod_{n=0}^p \left(2 \sum_{i=0}^{d_{n-1}+d_n+d_{n+1}-1} \left(egin{array}{c} m-1 \ i \end{array}
ight)
ight)^{S_n},$$

where we set $d_{-1} = d_{p+1} = 0$. We also note the 'trivial' upper bound, with $N := \sum_{n=0}^{p} S_n d_n$ and $M := \sum_{n=0}^{p} S_n m$,

$$R_{\mathrm{MPSN}} \leq 2 \sum_{j=0}^{N-1} \begin{pmatrix} M-1 \\ j \end{pmatrix}.$$

Moreover, if rank $((O_n)_{C:}) \ge \operatorname{rank}((M_n)_{C:})$ for any selection C of rows and $d_{n+1} \ge d_n$, for $n = 0, \ldots, p-1$, then for networks with outputs $H_0^{out}, \ldots, H_{p-1}^{out}$ we have

 $R_{\rm MPSN} \ge R_{\rm SCNN}$.

Strong Regular Graphs

Strongly Regular (SR) graphs represent 'hard' instances of graph isomorphism, as pairs thereof cannot provably be distinguished by the 3-WL test

Figure: Failure rate on the task of distinguishing SR graphs; logscale, the smaller the better. GIN fails to distinguish all graph pairs in all families.

Edge-Flow Classification

Synthetic flow as shown in the figure below.

Figure: Two samples from the two different classes of trajectories. The two trajectories correspond to approximately orthogonal directions in the space of harmonic functions of L_1 associated with the two holes.

Ocean drifter data with trajectories around the island of Madagascar between years 2011-2018 with the task to distinguish between the clockwise and counter-clockwise flows around the island.
